WHAT are Concrete Test Cylinders

Most commonly, the compressive strength of concrete is measured to ensure that concrete delivered to a project meets the requirements of the job specification and for quality control. For testing the compressive strength of concrete, cylindrical test specimens of size 4 × 8-inch (100 × 200-mm) or 6 × 12-inch (150 × 300-mm) are cast and stored in the field until the concrete hardens in accordance with the requirements of ASTM C 31, Standard Practice for Making and Curing Concrete Test Specimens in the Field.

Most specifications require that technicians certified by the ACI Field Testing Certification Grade I, or an equivalent program make test specimens in the field. When making cylinders for acceptance of concrete, the field technician must test other properties of the fresh concrete to include temperature, slump, density (unit weight) and air content. This information should accompany the set of cylinders made for a particular pour or pour location. A strength test result is always the average of at least two specimens tested at the same age. A set of 2 to 6 cylinders may be made from the same sample of concrete at a minimum for every 150 cubic yards (115 m³) of concrete placed.

WHY Make Concrete Test Cylinders

According to ASTM C 31, the results of standard-cured cylinders are used for

- Acceptance testing for specified strengths,
- Verifying mixture proportions for strength,
- Quality control by the concrete producer

It is of prime importance that the specimens are made and cured following standard procedures. Any deviation from standard procedures will result in a lower measured strength. Low strength test results due to procedures not in accordance with the standards cause undue concern, cost and delay to the project.

The strength results of field-cured cylinders are used for

- Determining the time at which a structure is permitted to be put into service,
- Evaluating the adequacy of curing and protecting concrete in the structure, and
- Scheduling removal of forms or shoring

Curing requirements for field-cured cylinders are different from standard curing and the two should not be confused. Refer to ASTM C 31 for details on curing field-cured specimens.

HOW to Make & Cure Cylinders

Equipment needed at the job site:

- Molds for casting cylinder specimens. Plastic molds are most common.
- Tamping rod with hemispherical tip - 5/8-inch (15-mm) diameter for 6 × 12-inch cylinders or 3/8-inch (10-mm) diameter for 4 × 8-inch cylinders, or a vibrator
- Rubber or rawhide mallet, 1.25 ± 0.50 lb. (0.6 ± 0.2 kg)
- Shovel, hand-held wooden float, and scoop,
- Wheelbarrow or other appropriate sample container,
- Water tank or curing box with provisions to maintain required curing environment during initial curing period.
- Safety equipment as appropriate to handle freshly mixed concrete.

Sampling concrete from a ready mixed concrete truck:

It is very important to obtain a sample of concrete that is representative of the concrete in the truck mixer. Sampling from concrete...
delivery units should be conducted in accordance with ASTM C 172
Standard Practice for Sampling Freshly Mixed Concrete. Concrete
should be sampled from the middle of the load. The first or last dis-
charge from the load will not provide a representative sample. The
concrete must be sampled by diverting the chute into a wheelbarrow
so that the entire discharge stream is collected. At least two portions
during discharge are necessary to obtain a composite sample. The
time elapsed between the first and final portion of the composite
sample must not exceed 15 minutes. The minimum required size of
the concrete sample is 1 cu. ft. (28 L).

Prior to Casting Cylinders:
Cover the sample with a plastic sheet to protect the concrete from
evaporation, sunlight, and contamination. Move the sample to the
location where the fresh concrete tests are to be conducted. The test-
ing location should be close to where the cylinders will be stored
undisturbed for the initial curing period. After the concrete is trans-
ported to the location for casting the cylinders, remix the concrete in
the wheelbarrow. Begin the slump, density (unit weight), and air con-
tent tests within 5 minutes and start molding cylinders within 15
minutes after the sample was obtained.

Casting the Test Cylinders:
- Label the outside of the mold with the appropriate identification
  mark. Do not label the lids or tops.
- Place the cylinder molds on a level surface
- Determine the method of consolidation
  1. For concrete with slump less than 1-inch (25-mm), concrete
     should be consolidated by vibration
  2. For concrete with slump 1-inch (25-mm) or higher, either
     rodding or vibrating is permitted.
- Determine the number of layers of concrete to be placed in the
  mold
  1. For concrete to be consolidated with the tamping rod, place
     concrete in 3 equal layers for 6 × 12-inch cylinders; and in 2
     equal layers for 4 × 8-inch cylinders
  2. For concrete to be consolidated by vibration, fill the mold in
two equal layers.
- Place the concrete in the mold by distributing it around the inside
  of the mold with the scoop. Consolidate the layer by rodding 25
  times evenly distributed around the layer. When using a vibrator,
  insert it long enough so the surface is smooth and large air pock-
  ets ceases to break through to the top. Two insertions of the
  vibrator are required for a 6 × 12-inch and one insertion is re-
  quired for a 4 × 8-inch cylinders. Avoid over vibration.
- Tap the sides of the mold 10-15 times with the mallet after each
  layer in order to close any insertion holes formed either by the
  rod or the vibrator.
- Strike off the top with a wooden float to produce a flat, even and
  level surface and cover with a plastic lid or a plastic bag.

Storing and transporting test cylinders:
- Move cylinder molds with fresh concrete very carefully by
  supporting the bottom
- Place the cylinders on a flat surface and in a controlled envi-
  ronment where the temperature is maintained in the range of
  60 to 80°F (16 to 27°C). When the specified strength of the
  concrete is greater than 6000 psi (40 MPa), the temperature
  range for initial curing should be maintained in the range of 68
to 78°F (20 to 26°C). Immersing cylinders, completely cov-
ered in water is an acceptable and preferred procedure that en-
sures more reliable strength results. Temperature in storage,
  such as in curing boxes, should be controlled using heating and
  cooling devices as necessary. The maximum and minimum tem-
  perature during initial curing should be recorded and reported.
- Protect cylinders from direct sunlight or radiant heat and from
  freezing temperatures in winter.
- Cylinders must be transported back to the laboratory within
  48 hours of casting. Some concrete mixtures may take longer
to set and these specimens may be transported at a later time.
  In any event cylinders should not be moved or transported
  until at least 8 hours after final set.

Store cylinders to prevent damage and maintain moisture during
transportation. Travel time from the jobsite to the laboratory should
not exceed 4 hours.

CAUTION
Fresh concrete can cause severe chemical burns to skin and eyes.
Keep fresh concrete off your skin. When working with concrete use
rubber work-boots, gloves, protective eyeglasses and clothing. Do
not let concrete or other cement-based products soak into clothing or
rub against your skin. Wash your skin promptly after contact with
fresh concrete with clean water. If fresh concrete gets into your eyes,
flush immediately and repeatedly with water. Consult a doctor imme-
diately. Keep children away from all freshley mixed plastic concrete.

Follow These Rules to Make and Cure Standard Cured Strength Test Specimens
1. Obtain a representative concrete sample
2. Place the concrete in layers in the molds and consolidate using standard equipment and procedures
3. Finish the surface smooth and cover the cylinder with a cap or plastic bag
4. For initial curing, store cylinders in the required temperature range. Protect from direct sunlight or extreme weather.
5. Transport the cylinders to the laboratory with proper protection within 48 hours after they are made.
